

Data link control \rightarrow Error control + Flow control

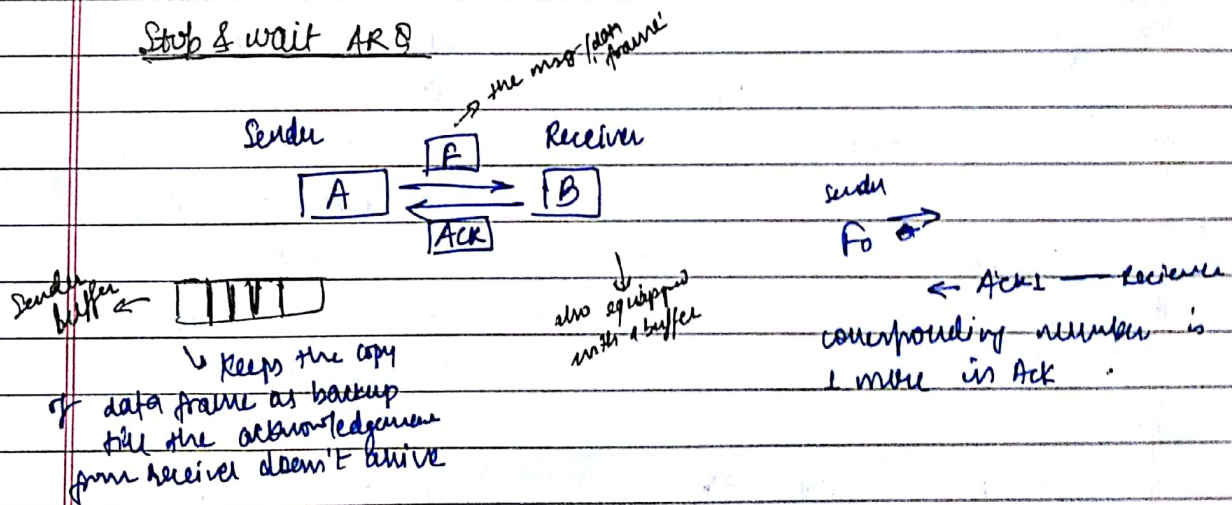

Error control by retransmission

Flow control -

- Transmission of message from sender to receiver whenever there is substantial speed difference b/w sender and receiver.
- Usually very fast sender and very slow receiver.
- There should be a mechanism of feedback from receiver to sender, so that sender can be notified to slow down the transmission then the data loss can be reduced. The solution to this is Automatic Repeat Request (ARQ).

Stop & wait ARQ

For a discarded msg and for a lost msg both, receiver doesn't send acknowledgement.

Control variable

S
001

R
001

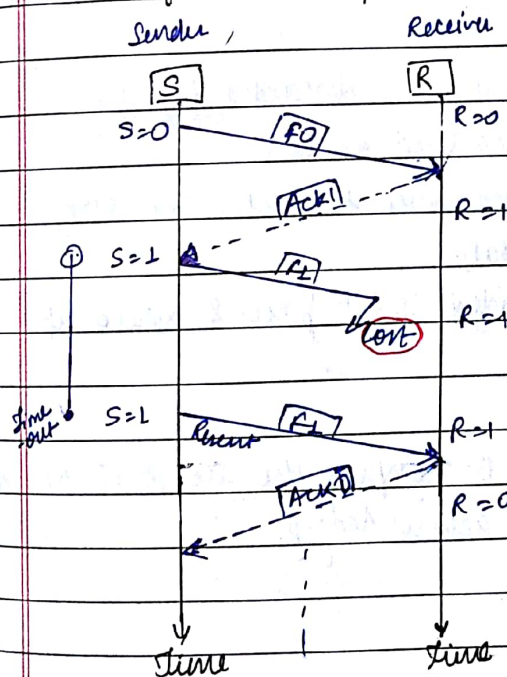

\rightarrow

value of R denotes the value of next frame expected.
value of R is changed when receiver successfully receives the frame.

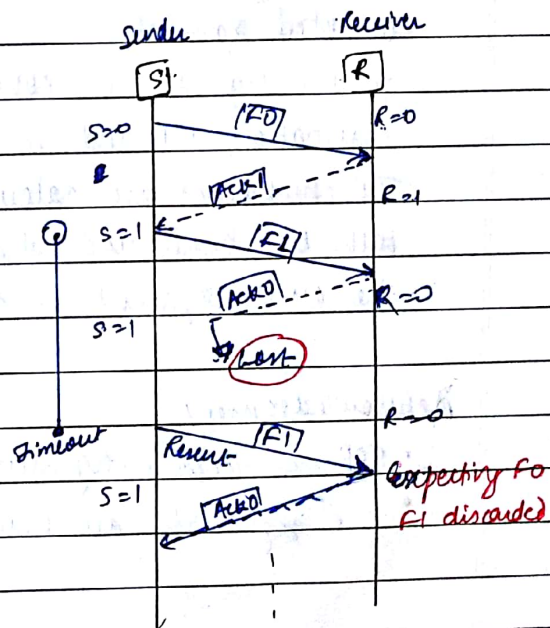

Normal operation

Damaged or lost frame

Lost acknowledgement

Sender resends **F1**, thinking it was not received. But receiver expected **F0**, so it discards **F1**. To prevent an infinite loop, receiver sends **Ack0**, so sender understands the previous transmission was successful.
